Please note: As part of the Fairchild Semiconductor integration, some of the Fairchild orderable part numbers will need to change in order to meet ON Semiconductor's system requirements. Since the ON Semiconductor product management systems do not have the ability to manage part nomenclature that utilizes an underscore (\_), the underscore (\_) in the Fairchild part numbers will be changed to a dash (-). This document may contain device numbers with an underscore (\_). Please check the ON Semiconductor website to verify the updated device numbers. ### 74VHC244 Octal Buffer/Line Driver with 3-STATE Outputs

### **General Description**

The VHC244 is an advanced high speed CMOS octal bus buffer fabricated with silicon gate CMOS technology. It achieves high speed operation similar to equivalent Bipolar Schottky TTL while maintaining the CMOS low power dissipation. The VHC244 is a non-inverting 3-STATE buffer having two active-LOW output enables. These devices are designed to be used as 3-STATE memory address drivers, clock drivers, and bus oriented transmitter/receivers.

An input protection circuit ensures that 0V to 7V can be applied to the input pins without regard to the supply voltage. This device can be used to interface 5V to 3V systems and two supply systems such as battery back up. This circuit prevents device destruction due to mismatched supply and input voltages.

### **Features**

- High Speed:  $t_{PD}$  = 3.9ns (typ) at  $V_{CC}$  = 5V
- High noise immunity: V<sub>NIH</sub> = V<sub>NIL</sub> = 28% V<sub>CC</sub> (min)
- Power down protection is provided on all inputs
- Low noise: V<sub>OLP</sub> = 0.6V (typ)
- Low power dissipation:  $I_{CC} = 4 \mu A \text{ (max)} @ T_A = 25 ^{\circ}C$
- Pin and function compatible with 74HC244

Note 1: Absolute Maximum Ratings are values beyond which the device may be damaged or have its useful life impaired. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. Fairchild does not recommend operation outside databook specifications

Note 2: Unused inputs must be held HIGH or LOW. They may not float.

Note 5:  $C_{PD}$  is defined as the value of the internal equivalent capacitance which is calculated from the operating current consumption without load. Average operating current can be obtained by the equation:  $I_{CC}$  (OPR.) =  $C_{PD}$  \*  $V_{CC}$  \*  $f_{IN}$  +  $I_{CO}$ /8 (per bit).
